Discussion

Embeddings

Definition

The embedding of a word w is a **dense** vector $\vec{v}(w) \in \mathcal{R}^k$ that represents semantic and other properties of w . Typical values are $50 \leq k \leq 1000$.

- ▶ In this respect, there is no difference to WordSpace: Both embeddings and WordSpace vectors are representations of words, primarily semantic, but also capturing other properties.
- ▶ Embeddings have much lower dimensionality than WordSpace vectors.
- ▶ WordSpace vectors are **sparse** (most entries are 0), embeddings **dense** (almost never happens that an entry is 0).

WordSpace

Word representations:

Density and dimensionality

- ▶ WordSpace vectors are **sparse** and **high-dimensional**.
- ▶ In contrast, embeddings are **dense** and **lower-dimensional**.
- ▶ Why are embeddings potentially better?
- ▶ Embeddings are more **efficient**.
- ▶ Embeddings are often more **effective**.

Efficiency of embeddings

High
dimensionality
→ slow
training

The time to
train a neural
network is
roughly linear
in the
dimensionality
of word
vectors.

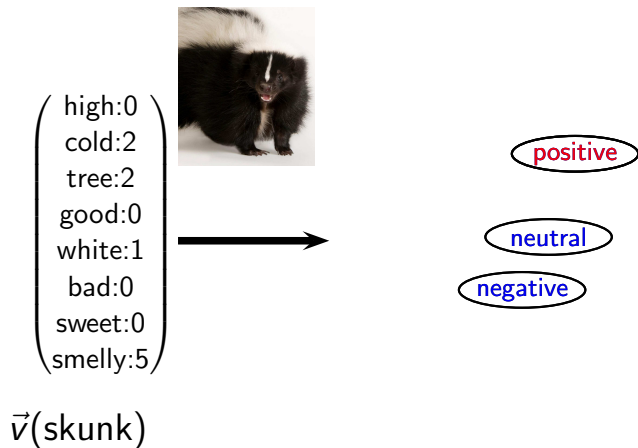

WordSpace vectors: Example for non-effectiveness

- ▶ Example: polarity classification
- ▶ Cooccurrence with “bad” indicates negative polarity.
- ▶ But corpora are often random and noisy and a negative word may not have occurred with “bad”.
- ▶ Possible result:
Incorrect classification based on WordSpace vectors
- ▶ Embeddings are more robust and “fill out” missing data.
- ▶ Details: below

Effectiveness of embeddings: Polarity

Effectiveness of embeddings: Polarity

Effectiveness of WordSpace: Thought experiment

- ▶ Construct an example of a corpus and two words w_1 and w_2 occurring in it having the following properties:
 - ▶ w_1 and w_2 are **semantically related**.
 - ▶ The WordSpace vectors of w_1 and w_2 are **not similar**.
- ▶ Goal: Embeddings eliminate failure modes of WordSpace.

Best-known embedding model: word2vec skipgram

- ▶ word2vec skipgram is
 - ▶ more **effective** than WordSpace
(embeddings and similarities of higher quality)
 - ▶ more **efficient** than WordSpace
(lower dimensionality)

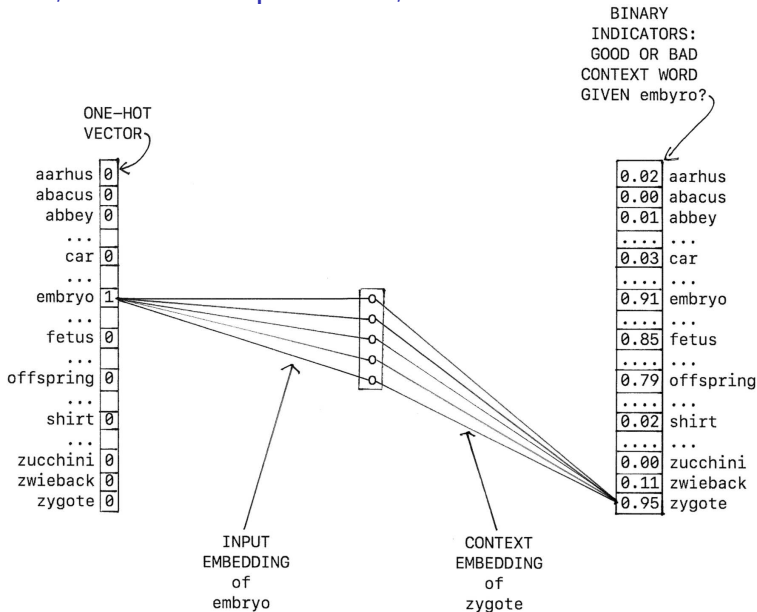

word2vec skipgram

predict, based on input word, a context word

word2vec skipgram

predict, based on input word, a context word

word2vec

learning = parameter estimation

- ▶ The embedding of a word is a real-valued vector $\in \mathcal{R}^k$.
- ▶ The coordinates are
parameters that we need to learn/estimate from the corpus.
- ▶ Learning of a WordSpace model:
(i) count, then (ii) PPML weighting
- ▶ For word2vec, learning is more complicated.
- ▶ Two different methods
 - ▶ Embeddings learned via matrix factorization
 - ▶ Embeddings learned via gradient descent
- ▶ These estimation methods are roughly equivalent.

Example of an embedding vector:

The numbers (or coordinates) are the parameters.

yoav.goldberg@gmail.com

Abstract

We analyze skip-gram with negative-sampling (SGNS), a word embedding method introduced by Mikolov et al., and show that it is implicitly factorizing a word-context matrix, whose cells are the pointwise mutual information (PMI) of the respective word and context pairs (shifted by a global constant). We find that another embedding method, NCE, is implicitly factorizing a similar matrix, where each cell is the (shifted) log conditional probability of a word given its context.

word2vec parameter estimation: Historical development vs. presentation in this lecture

- ▶ Mikolov et al. (2013) introduce word2vec, estimating parameters by gradient descent.
 - ▶ Still the learning algorithm used by default and in most cases
- ▶ Levy and Goldberg (2014) show near-equivalence to a particular type of matrix factorization.
 - ▶ Important because it links two important bodies of research:
[neural networks and distributional semantics](#)
- ▶ More natural progression in this lecture:
distributional semantics
 - embedding learning via matrix factorization
 - embedding learning via gradient descent

Dot product / scalar product

$$\vec{w} \vec{c} = \sum_i w_i c_i$$

Example:

$$\begin{pmatrix} w_1 \\ w_2 \\ w_3 \end{pmatrix} \cdot \begin{pmatrix} c_1 \\ c_2 \\ c_3 \end{pmatrix} = w_1 c_1 + w_2 c_2 + w_3 c_3$$

Outline of this section

- ▶ Recall:
We learn embedding parameters by [matrix factorization](#).
- ▶ We need an [input matrix](#) for matrix factorization.
- ▶ Brief recap on how to create the input matrix
- ▶ Also: link to information retrieval
- ▶ This type of “technology” comes from information retrieval.
- ▶ Brief overview of information retrieval setting

Vector representations:

Words vs. Documents/Queries

- ▶ Statistical NLP & Deep learning:
Embeddings as model for **word** similarity
- ▶ Information retrieval:
Vector representations as model of **query-document** similarity
- ▶ Simple search engine:
 - ▶ User enters query.
 - ▶ Query is transformed into query vector.
 - ▶ Documents are transformed into document vectors.
 - ▶ Order document vectors according to similarity to query
 - ▶ Return ranked list of documents to user:
The documents with highest similarity to query.

Basis for WordSpace: Cooccurrence→ Similarity

The similarity between two words is the cosine of the angle between them.

Small angle: silver and gold are similar. Medium-size angle: silver and society are not very similar. Large angle: silver and disease are even less similar.

Documents ranked according to similarity to query

Matrix factorization: Overview

- ▶ We will **decompose** the word-document matrix into a product of matrices.
- ▶ The particular decomposition we'll use: **singular value decomposition** (SVD).
- ▶ SVD: $C = U\Sigma V^T$ (where C = word-document matrix)
- ▶ We will then use the SVD to compute a **new, improved word-document matrix** C' .
- ▶ We'll get **better query-document similarity** values out of C' (compared to C).
- ▶ Using SVD for this purpose is called **latent semantic indexing** or LSI. □

Matrix factorization: Embeddings

- ▶ We will **decompose** the cooccurrence matrix into a product of matrices.
- ▶ The particular decomposition we'll use: **singular value decomposition** (SVD).
- ▶ SVD: $C = U\Sigma V^T$ (where C = cooccurrence matrix)
- ▶ We will then use the SVD to compute a **new, improved cooccurrence matrix** C' .
- ▶ We'll get **better word-word similarity** values out of C' (compared to C).

Example of $C = U\Sigma V^T$: The matrix C

C	d_1	d_2	d_3	d_4	d_5	d_6
ship	1	0	1	0	0	0
boat	0	1	0	0	0	0
ocean	1	1	0	0	0	0
wood	1	0	0	1	1	0
tree	0	0	0	1	0	1

We use a non-weighted matrix here to simplify the example.

Example of $C = U\Sigma V^T$: The matrix U

U	1	2	3	4	5
ship	-0.44	-0.30	0.57	0.58	0.25
boat	-0.13	-0.33	-0.59	0.00	0.73
ocean	-0.48	-0.51	-0.37	0.00	-0.61
wood	-0.70	0.35	0.15	-0.58	0.16
tree	-0.26	0.65	-0.41	0.58	-0.09

One row per word, one column per $\min(M, N)$ where M is the number of words and N is the number of documents.

This is an **orthonormal matrix**: (i) Row vectors have unit length.
(ii) Any two distinct row vectors are orthogonal to each other.

Think of the dimensions as “semantic” dimensions that capture distinct topics like politics, sports, economics. 2 = land/water

Each number u_{ij} in the matrix indicates how strongly related word i is to the topic represented by semantic dimension j . □

Example of $C = U\Sigma V^T$: The matrix Σ

Σ	1	2	3	4	5
1	2.16	0.00	0.00	0.00	0.00
2	0.00	1.59	0.00	0.00	0.00
3	0.00	0.00	1.28	0.00	0.00
4	0.00	0.00	0.00	1.00	0.00
5	0.00	0.00	0.00	0.00	0.39

This is a **square, diagonal matrix** of dimensionality $\min(M, N) \times \min(M, N)$.

The diagonal consists of the **singular values** of C .

The magnitude of the singular value measures the **importance of the corresponding semantic dimension**.

We'll make use of this by **omitting unimportant dimensions**.

Example of $C = U\Sigma V^T$: The matrix V^T

V^T	d_1	d_2	d_3	d_4	d_5	d_6
1	-0.75	-0.28	-0.20	-0.45	-0.33	-0.12
2	-0.29	-0.53	-0.19	0.63	0.22	0.41
3	0.28	-0.75	0.45	-0.20	0.12	-0.33
4	0.00	0.00	0.58	0.00	-0.58	0.58
5	-0.53	0.29	0.63	0.19	0.41	-0.22

One column per document, one row per $\min(M, N)$ where M is the number of words and N is the number of documents.

Again: This is an **orthonormal matrix**: (i) Column vectors have unit length. (ii) Any two distinct column vectors are orthogonal to each other.

These are again the semantic dimensions from matrices U and Σ that capture distinct topics like politics, sports, economics.

Each number v_{ij} in the matrix indicates how strongly related document i is to the topic represented by semantic dimension j .

Example of $C = U\Sigma V^T$: All four matrices (unreduced)

C	d_1	d_2	d_3	d_4	d_5	d_6											
ship	1	0	1	0	0	0	=										
boat	0	1	0	0	0	0											
ocean	1	1	0	0	0	0											
wood	1	0	0	1	1	0											
tree	0	0	0	1	0	1											
U	1	2	3	4	5	Σ		1	2	3	4	5					
ship	-0.44	-0.30	0.57	0.58	0.25	1	\times	2.16	0.00	0.00	0.00	0.00					
boat	-0.13	-0.33	-0.59	0.00	0.73	2		0.00	1.59	0.00	0.00	0.00					
ocean	-0.48	-0.51	-0.37	0.00	-0.61	3		0.00	0.00	1.28	0.00	0.00					
wood	-0.70	0.35	0.15	-0.58	0.16	4		0.00	0.00	0.00	1.00	0.00					
tree	-0.26	0.65	-0.41	0.58	-0.09	5		0.00	0.00	0.00	0.00	0.39					
V^T	d_1	d_2	d_3	d_4	d_5	d_6											
1	-0.75	-0.28	-0.20	-0.45	-0.33	-0.12											
2	-0.29	-0.53	-0.19	0.63	0.22	0.41											
3	0.28	-0.75	0.45	-0.20	0.12	-0.33											
4	0.00	0.00	0.58	0.00	-0.58	0.58											
5	-0.53	0.29	0.63	0.19	0.41	-0.22											

SVD is decomposition of C into a representation of the words, a representation of the documents and a representation of the importance of the "semantic" dimensions.

SVD: Summary

- ▶ We've decomposed the word-document matrix C into a product of three matrices: $U\Sigma V^T$.
- ▶ The word matrix U – consists of one (row) vector for each word
- ▶ The document matrix V^T – consists of one (column) vector for each document
- ▶ The singular value matrix Σ – diagonal matrix with singular values, reflecting importance of each dimension
- ▶ Next: Why are we doing this?

Property of SVD that we exploit here

- ▶ Key property:
Each singular value tells us how important its dimension is.
- ▶ By setting less important dimensions to zero, we keep the important information, but get rid of the “details”.
- ▶ These details may
 - ▶ be **noise** – in that case, reduced SVD vectors are a better representation because they are less noisy.
 - ▶ **make things dissimilar that should be similar** – again, reduced SVD vectors are a better representation because they represent similarity better.
- ▶ Analogy for “fewer details is better”
 - ▶ Image of a blue flower
 - ▶ Image of a yellow flower
 - ▶ Omitting color makes it easier to see the similarity

Reducing the dimensionality to 2

U	1	2	3	4	5	
ship	-0.44	-0.30	0.00	0.00	0.00	
boat	-0.13	-0.33	0.00	0.00	0.00	
ocean	-0.48	-0.51	0.00	0.00	0.00	
wood	-0.70	0.35	0.00	0.00	0.00	
tree	-0.26	0.65	0.00	0.00	0.00	
Σ_2	1	2	3	4	5	
1	2.16	0.00	0.00	0.00	0.00	
2	0.00	1.59	0.00	0.00	0.00	
3	0.00	0.00	0.00	0.00	0.00	
4	0.00	0.00	0.00	0.00	0.00	
5	0.00	0.00	0.00	0.00	0.00	
V^T	d_1	d_2	d_3	d_4	d_5	d_6
1	-0.75	-0.28	-0.20	-0.45	-0.33	-0.12
2	-0.29	-0.53	-0.19	0.63	0.22	0.41
3	0.00	0.00	0.00	0.00	0.00	0.00
4	0.00	0.00	0.00	0.00	0.00	0.00
5	0.00	0.00	0.00	0.00	0.00	0.00

Actually, we only zero out singular values in Σ . This has the effect of setting the corresponding dimensions in U and V^T to zero when computing the product $C = U\Sigma V^T$. \square

Reducing the dimensionality to 2

C_2	d_1	d_2	d_3	d_4	d_5	d_6
ship	0.85	0.52	0.28	0.13	0.21	-0.08
boat	0.36	0.36	0.16	-0.20	-0.02	-0.18

5	-0.53	0.29	0.63	0.19	0.41	-0.22

Example of $C = U\Sigma V^T$: All four matrices (unreduced)

C	d_1	d_2	d_3	d_4	d_5	d_6											
ship	1	0	1	0	0	0	=										
boat	0	1	0	0	0	0											
ocean	1	1	0	0	0	0											
wood	1	0	0	1	1	0											
tree	0	0	0	1	0	1											
U	1	2	3	4	5	Σ	1	2	3	4	5						
ship	-0.44	-0.30	0.57	0.58	0.25	1	2.16	0.00	0.00	0.00	0.00	\times					
boat	-0.13	-0.33	-0.59	0.00	0.73	2	0.00	1.59	0.00	0.00	0.00						
ocean	-0.48	-0.51	-0.37	0.00	-0.61	3	0.00	0.00	1.28	0.00	0.00						
wood	-0.70	0.35	0.15	-0.58	0.16	4	0.00	0.00	0.00	1.00	0.00						
tree	-0.26	0.65	-0.41	0.58	-0.09	5	0.00	0.00	0.00	0.00	0.39						
V^T	d_1	d_2	d_3	d_4	d_5	d_6											
1	-0.75	-0.28	-0.20	-0.45	-0.33	-0.12											
2	-0.29	-0.53	-0.19	0.63	0.22	0.41											
3	0.28	-0.75	0.45	-0.20	0.12	-0.33											
4	0.00	0.00	0.58	0.00	-0.58	0.58											
5	-0.53	0.29	0.63	0.19	0.41	-0.22											

SVD is decomposition of C into a representation of the words, a representation of the documents and a representation of the importance of the "semantic" dimensions.

Original matrix C vs. reduced $C_2 = U\Sigma_2V^T$

C	d_1	d_2	d_3	d_4	d_5	d_6
ship	1	0	1	0	0	0
boat	0	1	0	0	0	0
ocean	1	1	0	0	0	0
wood	1	0	0	1	1	0
tree	0	0	0	1	0	1

C_2	d_1	d_2	d_3	d_4	d_5	d_6
ship	0.85	0.52	0.28	0.13	0.21	-0.08
boat	0.36	0.36	0.16	-0.20	-0.02	-0.18
ocean	1.01	0.72	0.36	-0.04	0.16	-0.21
wood	0.97	0.12	0.20	1.03	0.62	0.41
tree	0.12	-0.39	-0.08	0.90	0.41	0.49

We can view C_2 as a **two-dimensional** representation of the matrix C . We have performed a **dimensionality reduction** to two dimensions.

Exercise

C	d_1	d_2	d_3	d_4	d_5	d_6
ship	1	0	1	0	0	0
boat	0	1	0	0	0	0
ocean	1	1	0	0	0	0
wood	1	0	0	1	1	0
tree	0	0	0	1	0	1

Compute the similarity between d_2 and d_3 for the original matrix and for the reduced matrix.

C_2	d_1	d_2	d_3	d_4	d_5	d_6
ship	0.85	0.52	0.28	0.13	0.21	-0.08
boat	0.36	0.36	0.16	-0.20	-0.02	-0.18
ocean	1.01	0.72	0.36	-0.04	0.16	-0.21
wood	0.97	0.12	0.20	1.03	0.62	0.41
tree	0.12	-0.39	-0.08	0.90	0.41	0.49

Why the reduced matrix C_2 is better than C

C	d_1	d_2	d_3	d_4	d_5	d_6
ship	1	0	1	0	0	0
boat	0	1	0	0	0	0
ocean	1	1	0	0	0	0
wood	1	0	0	1	1	0
tree	0	0	0	1	0	1
C_2	d_1	d_2	d_3	d_4	d_5	d_6
ship	0.85	0.52	0.28	0.13	0.21	-0.08
boat	0.36	0.36	0.16	-0.20	-0.02	-0.18
ocean	1.01	0.72	0.36	-0.04	0.16	-0.21
wood	0.97	0.12	0.20	1.03	0.62	0.41
tree	0.12	-0.39	-0.08	0.90	0.41	0.49

- ▶ Similarity of d_2 and d_3 in the original space: 0.
- ▶ Similarity of d_2 and d_3 in the reduced space:
 $0.52 * 0.28 + 0.36 * 0.16 + 0.72 * 0.36 + 0.12 * 0.20 + -0.39 * -0.08 \approx 0.52$

word2vec learning via matrix factorization

- ▶ Collect and weight cooccurrence matrix
- ▶ Compute SVD of cooccurrence matrix
- ▶ Reduce the space
- ▶ embeddings = left singular vectors (left matrix)

embeddings = left singular vectors

U	1	2	3	4	5	
ship	-0.44	-0.30	0.00	0.00	0.00	
boat	-0.13	-0.33	0.00	0.00	0.00	
ocean	-0.48	-0.51	0.00	0.00	0.00	
wood	-0.70	0.35	0.00	0.00	0.00	
tree	-0.26	0.65	0.00	0.00	0.00	
Σ_2	1	2	3	4	5	
1	2.16	0.00	0.00	0.00	0.00	
2	0.00	1.59	0.00	0.00	0.00	
3	0.00	0.00	0.00	0.00	0.00	
4	0.00	0.00	0.00	0.00	0.00	
5	0.00	0.00	0.00	0.00	0.00	
V^T	d_1	d_2	d_3	d_4	d_5	d_6
1	-0.75	-0.28	-0.20	-0.45	-0.33	-0.12
2	-0.29	-0.53	-0.19	0.63	0.22	0.41
3	0.00	0.00	0.00	0.00	0.00	0.00
4	0.00	0.00	0.00	0.00	0.00	0.00
5	0.00	0.00	0.00	0.00	0.00	0.00

Actually, we only zero out singular values in Σ . This has the effect of setting the corresponding dimensions in U and V^T to zero when computing the product $C = U\Sigma V^T$. \square

Optimality

- ▶ SVD is **optimal** in the following sense.
- ▶ Keeping the k largest singular values and setting all others to zero gives you the optimal approximation of the original matrix C . **Eckart-Young theorem**
- ▶ Optimal: no other matrix of the same rank (= with the same underlying dimensionality) approximates C better.
- ▶ Measure of approximation is Frobenius norm:
$$\|C - C'\|_F = \sqrt{\sum_i \sum_j (c_{ij} - c'_{ij})^2}$$
- ▶ So SVD uses the “best possible” matrix.
- ▶ There is only one best possible matrix – unique solution (modulo signs).
- ▶ Caveat: There is only a weak relationship between the Frobenius norm and cosine similarity between documents. □

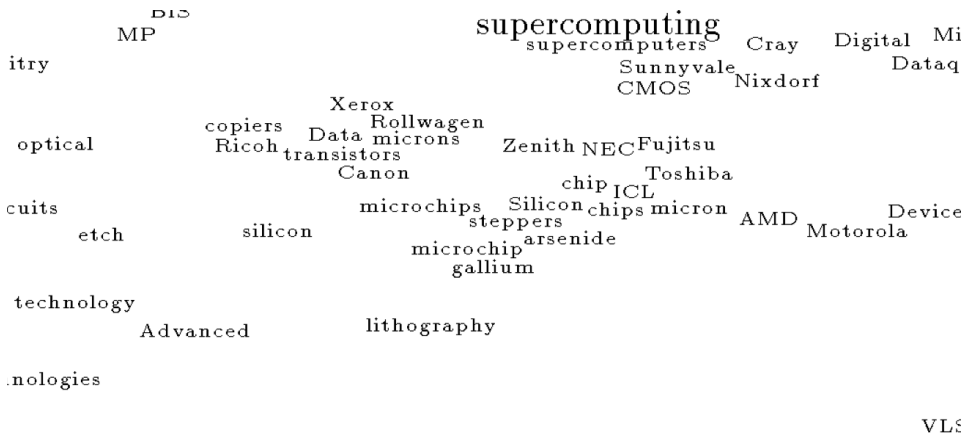

Embeddings (1): Vector space model (Salton, 1960s)

Embeddings (2): Latent Semantic Indexing (Deerwester, Dumais, Landauer . . . , 1980s)

Embeddings (3): SVD-based methods (Schütze, 1992)

The semantic field of *supercomputing* in sublexical space.

Embeddings (4):

Neural models (Bengio, Schwenk, . . . , 2000s)

Embeddings (5): word2vec

CBOW

Skip-gram

Embeddings (6):

SVD-based methods (Stratos et al., 2015)

2. Scale statistics to construct a matrix $\Omega \in \mathbb{R}^{n \times n}$:

SPECTRAL-TEMPLATE

Input: word-context co-occurrence counts $\#(w, c)$, dimension m , transformation method t , scaling method s , context smoothing exponent $\alpha \leq 1$, singular value exponent $\beta \leq 1$

Output: vector $v(w) \in \mathbb{R}^m$ for each word $w \in [n]$

Definitions: $\#(w) := \sum_c \#(w, c)$, $\#(c) := \sum_w \#(w, c)$, $N(\alpha) := \sum_c \#(c)^\alpha$

$$\Omega_{w,c} \leftarrow \begin{cases} \#(w, c) & \text{if } s = \text{—} \\ \frac{\#(w, c)}{\#(w)} & \text{if } s = \text{reg} \\ \max \left(\log \frac{\#(w, c) N(\alpha)}{\#(w) \#(c)^\alpha}, 0 \right) & \text{if } s = \text{ppmi} \\ \frac{\#(w, c)}{\sqrt{\#(w) \#(c)^\alpha}} \sqrt{\frac{N(\alpha)}{N(1)}} & \text{if } s = \text{cca} \end{cases}$$

1. Transform all $\#(w, c)$, $\#(w)$, and $\#(c)$:

$$\#(\cdot) \leftarrow \begin{cases} \#(\cdot) & \text{if } t = \text{—} \\ \log(1 + \#(\cdot)) & \text{if } t = \text{log} \\ \#(\cdot)^{2/3} & \text{if } t = \text{two-thirds} \\ \sqrt{\#(\cdot)} & \text{if } t = \text{sqrt} \end{cases}$$

Perform rank- m SVD on $\Omega \approx U \Sigma V^\top$ where $\Sigma = \text{diag}(\sigma_1, \dots, \sigma_m)$ is a diagonal matrix of ordered singular values $\sigma_1 \geq \dots \geq \sigma_m \geq 0$.

Define $v(w) \in \mathbb{R}^m$ to be the w -th row of $U \Sigma^\beta$ normalized to have unit 2-norm.

Embeddings (7): GloVe (Pennington, Socher, Manning, 2014)

$$J = \sum_{i,j=1}^V f(X_{ij})(w_i^T \tilde{w}_j + b_i + \tilde{b}_j - \log X_{ij})^2$$

Takeaway

Limitations of WordSpace

- ▶ WordSpace vectors can be inefficient.
(large number of parameters when used in deep learning)
- ▶ WordSpace vectors can be ineffective.
(due to randomness and noisiness of cooccurrence)

Takeaway

Definition of embedding

- ▶ Real-valued vector representation of word w
- ▶ Represents semantic and other properties of w
- ▶ Low dimensionality k (e.g., $50 \leq k \leq 1000$)
- ▶ Dense (as opposed to sparse)

Takeaway

Embeddings by matrix factorization

- ▶ Compute PPMI cooccurrence matrix
- ▶ Decompose it using SVD
- ▶ Reduce left matrix U to d dimensions
- ▶ Reduced U is then the embeddings matrix.
